

1 Abstract

Our goal is to learn

- Euler approximation for the solution of 1-d SDE
- Strong and weak convergence rate

2 Problem

Consider 1-d SDE

$$dX_t = \mu(X_t)dt + \sigma(X_t)dW_t, X(0) = x_0$$

We shall find, for some small step size δ

$$X^\delta(t) \approx X(t), \forall t \geq 0$$

in some sense. For convenience, we assume μ and σ are infinitely smooth and bounded in all its values and derivatives.

3 Euler scheme

The above SDE can be written as the following integral form:

$$X_t = x_0 + \int_0^t \mu(X_s)ds + \sigma(X_s)dW_s$$

If we denote

$$X_{t,s} = X_s - X_t,$$

then

$$X_{t,t+\delta} = \int_t^{t+\delta} \mu(X_s)ds + \sigma(X_s)dW_s.$$

Ito formula says

$$\mu(X_s) = \mu(X_t) + \int_t^s (\mu'(X_r) + \frac{1}{2}\mu''(X_r))dr + \mu'(X_r)\sigma(X_r)dW_r$$

and

$$\sigma(X_s) = \sigma(X_t) + \int_t^s (\sigma'(X_r) + \frac{1}{2}\sigma''(X_r))dr + \sigma'(X_r)\sigma(X_r)dW_r.$$

If $|s - t| < \delta$ is small enough, we expect $\int_t^s \dots$ is again small, and write

$$\mu(X_s) \approx \mu(X_t)$$

and

$$\sigma(X_s) \approx \sigma(X_t).$$

Thus, $X_{t,t+\delta}$ can be rewritten as

$$X_{t,t+\delta} \approx \mu(X_t)\delta + \sigma(X_t)W_{t,t+\delta}.$$

With the fact that $W_{i\delta, (i+1)\delta} \sim \sqrt{\delta}Z_i$ are iid normal random variables, Euler method repeats the following recursive formula:

$$X_{i\delta, (i+1)\delta}^\delta = \mu(X_{i\delta}^\delta)\delta + \sigma(X_{i\delta}^\delta)\sqrt{\delta}Z_i, \forall i = 0, \dots, N-1.$$

We can write the following pseudocode.

Algorithm 1 Euler for SDE 1d to simulate $\hat{X} \approx \langle X, \Pi_{T,N} \rangle$

```

1: inputs: drift  $\mu(\cdot)$  and volatility  $\sigma(\cdot)$ 
2: procedure EULER1D( $x, T, N$ ) ▷  $x$ : initial state,  $T$ : terminal time,
3: ▷  $N$ : number of meshes
4:    $\delta \leftarrow T/N$ ;  $X_0^\delta \leftarrow x$ ; ▷ Init
5:   for  $i = 0 \dots N-1$  do
6:      $t_{i+1} \leftarrow t_i + \delta$ 
7:      $Z \leftarrow \mathcal{N}(0, 1)$ 
8:      $X_{i+1}^\delta \leftarrow X_i^\delta + \mu(X_i^\delta)\delta + \sigma(X_i^\delta)\sqrt{\delta}Z$ 
9:   return  $\{(t_i, X_i^\delta) : i = 0, 1, \dots, N\}$ . ▷ output is a discrete path

```

4 Strong convergence rate

Algo 1 gives a sequence of numbers:

$$(X_0^\delta, X_1^\delta, \dots, X_N^\delta) := X^\delta.$$

To compare with continuous true path $(X_t : t \in [0, T])$, we first do the piecewise linear interpolation of X^δ , that is

$$L_t^\delta = \frac{(i+1)\delta - t}{\delta}X_i^\delta + \frac{t - i\delta}{\delta}X_{i+1}^\delta, \text{ if } i\delta \leq t < (i+1)\delta.$$

Theorem 1 *RMSE of Euler approximation under uniform norm has convergence order 1/2, i.e.*

$$\mathbb{E} \left[\sup_{0 \leq t \leq T} |X_t - L_t^\delta| \right] \leq K\delta^{1/2}.$$

PROOF: see Theorem 2.7.3 of [2]. \square

ex. Show that

$$\mathbb{E}[|X_T - L_T^\delta|] \leq K\delta^{1/2}.$$

4.1 A remark on constant interpolation of Euler solution

If we denote the piecewise constant interpolation by

$$C_t^\delta = X_i^\delta, \text{ if } i\delta \leq t < (i+1)\delta,$$

then the above strong convergence fails. Let's use the following example to illustrate this issue.

Let $X = W$ be the Brownian motion itself. Euler yields

$$C_t^\delta = W_{[t/\delta]\delta}.$$

Therefore,

$$RMSE = \mathbb{E} \left[\sup_{0 \leq t \leq T} |X_t - C_t^\delta| \right] = \mathbb{E} \left[\sup_{0 \leq t \leq T} |W_t - W_{[t/\delta]\delta}| \right] = \mathbb{E} \left[\sup_{i=0, \dots, N-1} Y_i \right],$$

where

$$Y_i = \sup_{i\delta \leq t < (i+1)\delta} |W_t - W_{i\delta}|.$$

Note $Y_i \geq |W_{i\delta, (i+1)\delta}| := \sqrt{\delta} |Z_i|$, then

$$RMSE \geq \sqrt{\delta} \mathbb{E} \left[\sup_{i=0, \dots, N-1} |Z_i| \right] > O(\delta^{1/2}).$$

5 Weak convergence rate

Given Y^δ and X , we define

$$e^g(\delta) = \left| \mathbb{E}[g(X_T)] - \mathbb{E}[g(Y_T^\delta)] \right|.$$

Then, we say Y_T^δ converges to X_T weakly if

$$\lim_{\delta \rightarrow 0} e^g(\delta) = 0, \quad \forall g \in C_b.$$

We say weak convergence rate is γ , if

$$\exists K_g > 0, \text{ s.t. } e^g(\delta) \leq K_g \delta^\gamma$$

for any $g \in C_b$.

Theorem 2 C^δ converges to X with $\gamma = 1$.

PROOF: see section 9.7 of [1] \square

5.1 Exercise

Example 1 Consider CEV

$$dS_t = 0.03S_t dt + \sigma S_t^\gamma dW_t, \quad S_0 = 100.$$

- Write a pseudo code and python code for vanilla option price
- For $\sigma = 0.2$ and $\gamma = 1$, compute call price with $T = 1$ and $K = 97$. Does it recover option price given by BSM formula?
- (optional) can you demonstrate the weak/strong convergence rate
- Download option data from [here](#) and calibrate volatility and elasticity constant from 5 month call options.
